LUA-WIDOW-CONTROL

Max Chernoff

v 3.0.0

---

ctan.org/pkg/lua-widow-control
github.com/gucci-on-fleek/lua-widow-control

Lua-widow-control is a Plain TEX/LATEX/ConTEXt/OpTEX package that removes widows and orphans without any user intervention. Using the power of LuaTEX, it does so *without* stretching any glue or shortening any pages or columns. Instead, lua-widow-control automatically lengthens a paragraph on a page or column where a widow or orphan would otherwise occur.

QUICK START

Ensure that your TEX Live/MikTEX distribution is up-to-date. Then, LATEX users just need to place `\usepackage{lua-widow-control}` in the preamble of their document. For more details, see the **Usage sections**.

CONTENTS

PRELIMINARIES

This manual begins with a brief introduction to widows, orphans, and lua-widow-control. For an extended introduction and discussion of these topics, please see the *Zpravodaj* article[1] distributed with this manual (Links: **local**, **CTAN**, **GitHub**). This same material is also available in two *TUGboat* articles[2,3] (Links: **local**, **CTAN**, **GitHub**) if you prefer. You can also skip ahead to the **installation instructions on page 7** or the **usage section starting at page 8**.

MOTIVATION

Unmodified TEX has only two familiar ways of dealing with widows and orphans: it can either shorten a page by one line, or it can stretch vertical whitespace. TEX was designed for mathematical and scientific typesetting, where a typical page has multiple section headings, tables, figures, and equations. For this style of document, TEX's default behaviour works quite well, since the slight stretching of whitespace between the various document elements is nearly imperceptible; however, for prose or other documents composed almost entirely of paragraphs, there is little vertical whitespace to stretch.

Lua-widow-control offers an alternative method of removing widows and orphans: instead of shortening a page or stretching vertical whitespace, lua-widow-control simply chooses a paragraph to lengthen by one line such that the widow or orphan is eliminated.

WIDOWS AND ORPHANS

Widows

A "widow" occurs when the majority of a paragraph is on one page or column, but the last line is on the following page or column. It not only looks quite odd for a lone line to be at the start of the page, but it makes a paragraph harder to read since the separation of a paragraph and its last line disconnects the two, causing the reader to lose context for the widowed line.

Orphans An "orphan" occurs when the first line of a paragraph is at the end of the page or column preceding the remainder of the paragraph. They are not as distracting for the reader, but they are still not ideal. Visually, widows and orphans are about equally disruptive; however, orphans tend not to decrease the legibility of a text as much as widows, so some authors choose to ignore them.

Broken Hyphens "Broken" hyphens occur whenever a page break occurs in a hyphenated word. These are not related to widows and orphans; however, breaking a word across two pages is at least as disruptive for the reader as widows and orphans. TEX identifies broken hyphens in the same ways as widows and orphans, so lua-widow-control treats broken hyphens in the same way.

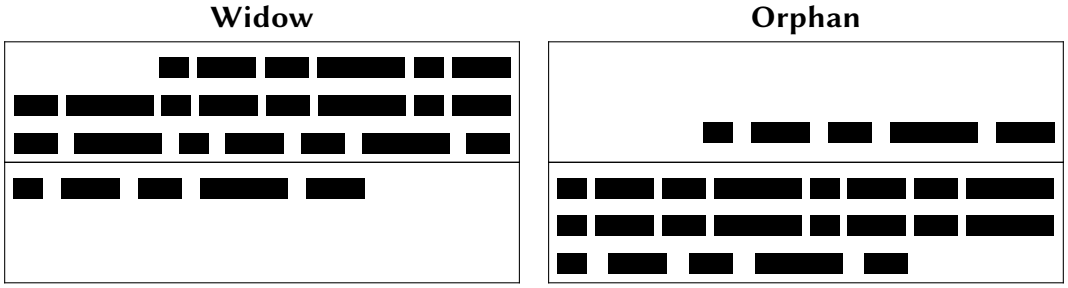

Figure 1 A visual comparison of widows and orphans.

TEX'S PAGINATION

Algorithm It is tricky to understand how lua-widow-control works if you aren't familiar with how TEX breaks pages and columns. For a full description, you should consult Chapter 15 of *The TEXBook*[4] ("How TEX Makes Lines into Pages"); however, this goes into much more detail than most users require, so here is a *very* simplified summary of TEX's page breaking algorithm:

TEX fills the page with lines and other objects until the next object will no longer fit. Once no more objects will fit, TEX will align the bottom of the last line with the bottom of the page by stretching any available vertical spaces if (in LATEX) `\flushbottom` is set; otherwise, it will break the page and leave the bottom empty.

However, some objects have "penalties" attached. Penalties encourage or discourage page breaks from occurring at specific places. For example, LATEX sets a negative penalty before section headings to encourage a page break there; conversely, it sets a positive penalty after section headings to discourage breaking.

To reduce widows and orphans, TEX sets weakly-positive penalties between the first and second lines of a paragraph to prevent orphans, and between the penultimate and final lines to prevent widows.

Behaviour Due to these "penalties" attached to widows and orphans, TEX tries to avoid creating them. Widows and orphans with small penalties attached—like LATEX's default values of 150—are only lightly coupled to the rest of the paragraph, while widows and orphans with large penalties—values of 10 000 or more—are treated as infinitely bad and are thus unbreakable. Intermediate values behave just as you would expect, discouraging page breaks proportional to their value.

However, when these lines are moved as a group, TEX will have to make a page or column with less lines. "**Demonstration**" goes into further detail about how TEX deals with these too-short pages or columns.

DEMONSTRATION

Although TEX's page breaking algorithm is reasonably straightforward, it can lead to complex behaviour when widows and orphans are involved. The usual choices, when rewriting is not possible, are to ignore them, stretch some glue, or shorten the page. **Table 1** has a visual comparison of these options, which we'll discuss in the following:

"Ignore" As you can see, the last line of the page is on a separate page from the rest of its paragraph, creating a widow. This is usually highly distracting for the reader, so it is best avoided for the reasons previously discussed.

"Shorten" This page did not leave any widows, but it did shorten the previous page by one line. Sometimes this is acceptable, but usually it looks bad because pages will then have different text-block heights. This can make the pages look quite uneven, especially when typesetting with columns or in a book with facing pages.

"Stretch" This page also has no widows and it has a flush bottom margin. However, the space between each pair of paragraphs had to be stretched.

If this page had many equations, headings, and other elements with natural space between them, the stretched out space would be much less noticeable. TEX was designed for mathematical typesetting, so it makes sense that this is its default behaviour. However, in a page with mostly text, these paragraph gaps look unsightly.

Also, this method is incompatible with grid typesetting, where all glue stretching must be quantised to the height of a line.

Ignore	Shorten	Stretch	Lua-widow-control
Lua-widow-control can remove most widows and orphans from a document, *without* stretching any glue or shortening any pages. It does so by automatically lengthening a paragraph on a page where a widow or orphan would otherwise occur. While TEX breaks paragraphs into their natural length, lua-widow-control is breaking the paragraph 1 line longer than its natural length. TEX's paragraph is output to the page, but lua-widow-control's paragraph is just stored for later. When a widow or orphan occurs, lua-widow-control can take over. It selects the previously-saved paragraph with the least badness; then, it replaces TEX's paragraph with its saved paragraph. This increases the text block height of the page by 1 line. Now, the last line of the current page can be pushed to the top of the next page. This removes the widow or the orphan without creating any additional work.	Lua-widow-control can remove most widows and orphans from a document, *without* stretching any glue or shortening any pages. Table 1 A visual comparison of various automated widow handling techniques.

"lua-widow-control"

Lua-widow-control has none of these issues: it eliminates the widows in a document while keeping a flush bottom margin and constant paragraph spacing.

To do so, lua-widow-control lengthened the second paragraph by one line. If you look closely, you can see that this stretched the interword spaces. This stretching is noticeable when typesetting in a narrow text block, but is mostly imperceptible with larger widths.

Lua-widow-control automatically finds the "best" paragraph to stretch, so the increase in interword spaces should almost always be minimal.

INSTALLATION

Most up-to-date TEX Live and MikTEX systems should already have lua-widow-control installed. However, a manual installation may occasionally be required.

TEX Live

Run `tlmgr install lua-widow-control` in a terminal, or install using the "TEX Live Manager" GUI.

MikTEX

Run `mpm --install=lua-widow-control` in a terminal, or install using the "MikTEX Maintenance" GUI.

Manual

Currently, ConTEXt MkXL (LuaMetaTEX) users must manually install the package. Most other users will be better served by using the lua-widow-control supplied by TEX Live and MikTEX; however, all users may manually install the package if desired. The procedure should be fairly similar regardless of your OS, TEX distribution, or format.

Steps

1. Download `lua-widow-control.tds.zip` from **CTAN**, **GitHub** or the **ConTEXt Garden**.
2. Unzip the release into your `TEXMFLOCAL/` directory. (You can find its location by running `kpsewhich --var-value TEXMFHOME` in a terminal)
3. Refresh the filename database:
   - ConTEXt: `mtxrun --generate`
   - TEX Live: `mktexlsr`
   - MikTEX: `initexmf --update-fndb`

DEPENDENCIES

Lua-widow-control does have a few dependencies; however, these will almost cer-

tainly be met by all but the most minimal of TEX installations.

Plain TEX Lua-widow-control requires LuaTEX (≥ 0.85) and the most recent version of luatexbase (2015/10/04). Any version of TEX Live ≥ 2016 will meet these requirements.

LATEX Lua-widow-control requires LuaTEX (≥ 0.85), LATEX (≥ 2020/10/01), and microtype (any version). Any version of TEX Live ≥ 2021 will meet these requirements.

Lua-widow-control also supports a "legacy" mode for older LATEX kernels. This uses an older version of the LATEX code while still using the most recent Lua code. This mode requires LuaTEX (≥ 0.85), LATEX (≥ 2015/01/01), microtype (any version), and etoolbox (any version). Any version of TEX Live ≥ 2016 will meet these requirements.

Please note that when running in legacy mode, you cannot use the key–value interface. This legacy interface is undocumented, but mostly the same as the "Plain TEX" interface.

ConTEXt Lua-widow-control supports both ConTEXt MkXL (LuaMetaTEX) and ConTEXt MkIV (LuaTEX).

OpTEX Lua-widow-control works with any version of OpTEX and has no dependencies.

LuaMetaTEX Lua-widow-control has preliminary support for LuaMetaLATEX and LuaMetaPlain. All features should work identically to the LuaTEX-based version, although there are a few minor bugs. You should always make sure to use the latest engine, format, and lua-widow-control since these formats are under rapid development.

LOADING THE PACKAGE

Plain TEX	`\input lua-widow-control`
LATEX	`\usepackage{lua-widow-control}`
ConTEXt	`\usemodule[lua-widow-control]`
OpTEX	`\load[lua-widow-control]`

OPTIONS

Lua-widow-control is automatically enabled with the default settings as soon as you load it. Most users should not need to configure lua-widow-control; however, the packages provides a few commands.

Overview

LaTeX users can set the options either when loading the package (`\usepackage[⟨options⟩]{lua-widow-control}`) or at any point using `\lwcsetup{⟨options⟩}`.

ConTeXt users should use the `\setuplwc[⟨options⟩]` command for setting options at any point.

Plain TeX and OpTeX are a little different. Some options require you to set a register (i.e., `\lwcemergencystretch = ⟨dimension⟩`), while others use macro arguments (i.e., `\lwcnobreak{⟨option⟩}`).

Disabling

You may want to disable lua-widow-control for certain portions of your document. You can do so with the following commands:

Plain TeX/OpTeX	`\lwcdisable`
LaTeX	`\lwcsetup{disable}`
ConTeXt	`\setuplwc[state = stop]`

This prevents lua-widow-control from stretching any paragraphs that follow. If a page has earlier paragraphs where lua-widow-control was still enabled and a widow or orphan is detected, lua-widow-control will still attempt to remove the widow or orphan.

Enabling

Lua-widow-control is enabled as soon as the package is loaded. If you have previously disabled it, you will need to re-enable it to save new paragraphs.

Plain TeX/OpTeX	`\lwcenable`
LaTeX	`\lwcsetup{enable}`
ConTeXt	`\setuplwc[state = start]`

Automatically disabling

You may want to disable lua-widow-control for certain commands where stretching is undesirable such as section headings. Of course, manually disabling and then enabling lua-widow-control multiple times throughout a document would quickly become tedious, so lua-widow-control provides some options to do this automatically for you.

Lua-widow-control automatically patches the default LaTeX, ConTeXt, Plain TeX, OpTeX, memoir, KOMA-Script, and titlesec section commands, so you don't need to patch these. Any others, though, you'll need to patch yourself.

Plain TEX/OpTEX	`\lwcdisablecmd ⟨\macro⟩`
LATEX	`\lwcsetup{disablecmds = {⟨macronameone⟩, ⟨macronametwo⟩}}`
ConTEXt	`\prependtoks\lwc@patch@pre\to\everybefore⟨hook⟩`
	`\prependtoks\lwc@patch@pre\to\everyafter⟨hook⟩`

The Plain TEX, OpTEX, and ConTEXt commands *append* to the list of patched commands: they simply patch the provided commands while leaving the original patches in place. The LATEX option *sets* the list of patched commands: it replaces the default list with the provided list.

\emergencystretch

Lua-widow-control defaults to an `\emergencystretch` value of 3 em for stretched paragraphs, but you can configure this.

Lua-widow-control will only use the `\emergencystretch` when it cannot lengthen a paragraph in any other way, so it is fairly safe to set this to a large value. TEX accumulates badness when `\emergencystretch` is used, so it's pretty rare that a paragraph that requires any `\emergencystretch` will actually be used on the page.

Plain TEX/OpTEX	`\lwcemergencystretch = ⟨dimension⟩`
LATEX	`\lwcsetup{emergencystretch = ⟨dimension⟩}`
ConTEXt	`\setuplwc[emergencystretch = ⟨dimension⟩]`

Penalties

You can also manually adjust the penalties that TEX assigns to widows and orphans. Usually, the defaults are fine, but there are a few circumstances where you may want to change them.

Plain TEX/OpTEX	`\widowpenalty = ⟨integer⟩`
	`\clubpenalty = ⟨integer⟩`
	`\brokenpenalty = ⟨integer⟩`
LATEX	`\lwcsetup{widowpenalty = ⟨integer⟩}`
	`\lwcsetup{orphanpenalty = ⟨integer⟩}`
	`\lwcsetup{brokenpenalty = ⟨integer⟩}`
ConTEXt	`\setuplwc[widowpenalty = ⟨integer⟩]`
	`\setuplwc[orphanpenalty = ⟨integer⟩]`
	`\setuplwc[brokenpenalty = ⟨integer⟩]`

The value of these penalties determines how much TEX should attempt to stretch glue before passing the widow or orphan to lua-widow-control. If you set the values to 1 (default), TEX will stretch nothing and immediately trigger lua-widow-control; if you set the values to 10 000, TEX will stretch infinitely and lua-widow-control will never be triggered. If you set the value to some intermediate number, TEX will first attempt to stretch some glue to remove the widow or orphan; only if it fails will lua-widow-control come in and lengthen a paragraph. As a special case, if you set the values to 0, both TEX and lua-widow-control will completely ignore the widow or orphan.

Lua-widow-control will pick up on the values of `\widowpenalty`, `\clubpenalty`, and `\brokenpenalty` regardless of how you set them, so the use of these dedicated keys is entirely optional.

`\nobreak` Behaviour

When lua-widow-control encounters an orphan, it removes it by moving the orphaned line to the next page. The majority of the time, this is an appropriate solution. However, if the orphan is immediately preceded by a section heading (or `\nobreak`/`\penalty 10000`), lua-widow-control would naïvely separate a section heading from the paragraph that follows. This is almost always undesirable, so lua-widow-control provides some options to configure this.

Plain TEX/OpTEX	`\lwcnobreak{`⟨*value*⟩`}`
LATEX	`\lwcsetup{nobreak = `⟨*value*⟩`}`
ConTEXt	`\setuplwc[nobreak = `⟨*value*⟩`]`

The default value, `keep`, *keep*s the section heading with the orphan by moving both to the next page. The advantage to this option is that it removes the orphan and retains any `\nobreak`s; the disadvantage is that moving the section heading can create a large blank space at the end of the page.

The value `split` *split*s up the section heading and the orphan by moving the orphan to the next page while leaving the heading behind. This is usually a bad idea, but exists for the sake of flexibility.

The value `warn` causes lua-widow-control to give up on the page and do nothing, leaving an orphaned line. Lua-widow-control *warn*s the user so that they can manually remove the orphan.

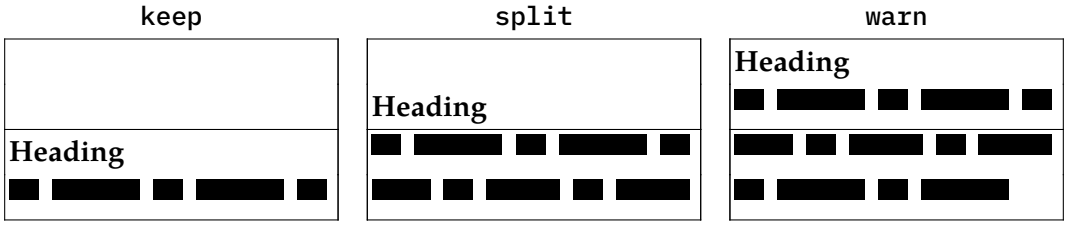

Figure 2 A visual comparison of the various `nobreak` options, where each box represents a different page.

Maximum Cost

Lua-widow-control ranks each paragraph on the page by how much it would "cost" to lengthen that paragraph. By default, lua-widow-control selects the paragraph on the page with the lowest cost; however, you can configure it to only select paragraphs below a selected cost.

If there aren't any paragraphs below the set threshold, then lua-widow-control won't remove the widow or orphan and will instead issue a warning.

Plain TEX/OpTEX	`\lwcmaxcost = ⟨integer⟩`
LATEX	`\lwcsetup{max-cost = ⟨integer⟩}`
ConTEXt	`\setuplwc[maxcost = ⟨integer⟩]`

Based on my testing, `max-cost` values less than 1 000 cause completely imperceptible changes in interword spacing; values less than 5 000 are only noticeable if you are specifically trying to pick out the expanded paragraph on the page; values less than 15 000 are typically acceptable; and larger values may become distracting. Lua-widow-control defaults to an infinite `max-cost`, although the "strict" and "balanced" modes sets the values to 5 000 and 10 000 respectively.

Lua-widow-control uses a "cost function" C that is initially defined as

$$C = \frac{d}{\sqrt{l}}$$

where d is the total demerits of the paragraph, and l is the number of lines in the paragraph.

Draft Mode

You can use the draft mode to visualize how lua-widow-control processes pages. Any remaining widows and orphans will be coloured red, any expanded paragraphs will be coloured green, and any lines moved to the next page will be coloured blue. In addition, the cost of each paragraph is shown in the right margin as it is here. 1846

Plain TEX/OpTEX	`\lwcdraft 1`
LATEX	`\lwcsetup{draft}`
ConTEXt	`\setuplwc[draft = start]`

1846

Advanced users may also customize the colours used by modifying the **`lwc.colours`** table. The table keys are currently `expanded`, `failure`, `moved`, and `cost`. The table values are RGB 3-tuples, where each element is a float between zero and one. infinite

You can also show or hide the costs and colours independently of each other. 8895

Plain TEX/OpTEX	`\lwcshowcosts 1`
	`\lwcshowcolours 1`
LATEX	`\lwcsetup{showcosts = true}`
	`\lwcsetup{showcolours = true}`
ConTEXt	`\setuplwc[showcosts = start]`
	`\setuplwc[showcolours = start]`

8895

Plain TEX users will need to modify their output routines to be able to see the costs. Before you ship out the page, you should call `\lwcpreshipout` with a box number as its argument. For example, here is some sample code to correctly reproduce the standard Plain TEX output routine: 57175

```
\newbox\tempshipoutbox                                  infinite
\output={                                               infinite
    \setbox\tempshipoutbox=\vbox{                       infinite
        \makeheadline                                   infinite
        \pagebody                                       infinite
        \makefootline                                   infinite
    }                                                   infinite
    \lwcpreshipout\the\tempshipoutbox                   infinite
    \shipout\box\tempshipoutbox                         infinite
    \advancepageno                                      infinite
}                                                       infinite
```

Setting the output routine like this is automatic in all other formats. Lua-widow-control does not modify the output routine in Plain TEX since most of its users likely have their own output routines.

Draft Offset

In draft mode, the paragraph costs are printed in the margins, offset a certain distance from the page edge. By default, this offset is set to 1 inch; however, you can change this to any value that you want:

Plain TEX/OpTEX	`\lwcdraftoffset = ⟨dimension⟩`
LATEX	`\lwcsetup{draftoffset = ⟨dimension⟩}`
ConTEXt	`\setuplwc[draftoffset = ⟨dimension⟩]`

Debug Mode

Lua-widow-control offers a "debug" mode that prints extra information in the log files. This may be helpful to understand how lua-widow-control is processing paragraphs and pages, although the information is likely inscrutable unless you are the package's author. If you are reporting an issue with lua-widow-control, make sure to compile your document with debug mode enabled!

Plain TEX/OpTEX	`\lwcdebug 1`
	`\lwcdebug 0`
LATEX	`\lwcsetup{debug = true}`
	`\lwcsetup{debug = false}`
ConTEXt	`\setuplwc[debug = start]`
	`\setuplwc[debug = stop]`

PRESETS

As you can see, lua-widow-control provides quite a few options. Luckily, there are a few presets that you can use to set multiple options at once. These presets are a good starting point for most documents, and you can always manually override individual options.

Presets are available only with LATEX and ConTEXt.

LATEX	`\lwcsetup{⟨preset⟩}`
ConTEXt	`\setuplwc[⟨preset⟩]`

`default` If you use lua-widow-control without any options, it defaults to this preset. In default mode, lua-widow-control takes all possible measures to remove widows and orphans and will not attempt to stretch any vertical glue. This usually removes $>95\%$ of all possible widows and orphans. The catch here is that this mode is quite aggressive, so it often leaves behind some fairly "spacey" paragraphs.

This mode is good if you want to remove (nearly) all widows and orphans from your document, without fine-tuning the results.

`strict` Lua-widow-control also offers a strict mode. This greatly restricts lua-widow-control's tolerance and makes it so that it will only lengthen paragraphs where the change will be imperceptible.

The caveat with strict mode is that—depending on the document— lua-widow-control will be able to remove less than a third of the widows and orphans. For the widows and orphans that can't be automatically removed, a warning will be printed to your terminal and log file so that a human can manually fix the situation.

This mode is good if you want the best possible typesetting and are willing to do some manual editing.

`balanced` Balanced mode sits somewhere between default mode and strict mode. This mode first lets TEX stretch a little glue to remove the widow or orphan; only if that fails will it then trigger lua-widow-control. Even then, the maximum paragraph cost is capped. Here, lua-widow-control can usually remove 90% of a document's potential widows and orphans, and it does so while making a minimal visual impact.

This mode is recommended for most users who care about their document's typography. This mode is not the default since it doesn't remove all widows and orphans: it still requires a little manual intervention.

LUA INTERFACE

Lua-widow-control provides a few public functions and tables that you can safely use or modify as documented. Any Lua interfaces that aren't documented below are subject to change at any time, but ff you do want to use an undocumented interface, please let me know and can easily document it.

Option	default	balanced	strict
max-cost	∞	10000	5000
emergencystretch	3em	1em	0pt
nobreak	keep	keep	warn
widowpenalty	1	500	1
orphanpenalty	1	500	1
brokenpenalty	1	500	1

Table 2 Lua-widow-control options set by each mode.

Costs

Lua-widow-control uses a "cost function" to select which paragraph to expand. Typically, this depends on the number of lines and demerits in the broken paragraph; however, you can redefine this function to do something else if you want. The default function is defined as:

```
--- The "cost function" to use.
---
--- @param demerits number The demerits of the broken paragraph
--- @param lines number The number of lines in the broken paragraph
--- @param nat_demerits number The demerits of the naturally-broken paragraph
--- @param nat_lines number The number of lines in the naturally-broken paragraph
--- @param head node The head of the broken paragraph
--- @return number cost The cost of the broken paragraph
function lwc.paragraph_cost(demerits, lines, nat_demerits, nat_lines,
head)
    return demerits / math.sqrt(lines)
end
```

Activation

Typically, lua-widow-control determines if there are widows and orphans at the end of a page by checking the `\outputpenalty` register. However, you can use a custom check if you want. The default check is defined as:

```
--- Determines if we should "activate" lwc for the current page/column.
---
--- @param penalty number The \outputpenalty for the current page/column
```

```
--- @param paragraphs table<table<string, node|number>> The `paragraphs` table
--- @param head node The head of the current page/column
--- @return boolean activate True if lwc should move the last line on this page
function lwc.should_remove_widows(penalty, paragraphs, head)
    return is_matching_penalty(penalty)
end
```

By setting a custom activation and cost function, you can transform lua-widow-control from a widow and orphan remover into a custom layout customization tool.

COMPATIBILITY

The lua-widow-control implementation is almost entirely in Lua, with only a minimal TEX footprint. It doesn't modify the output routine, `\everypar`, and it doesn't insert any whatsits. This means that it should be compatible with nearly any TEX package, class, and format. Most changes that lua-widow-control makes are not observable on the TEX side.

However, on the Lua side, lua-widow-control modifies much of a page's internal structure. This should not affect any TEX code; however, it may surprise Lua code that modifies or depends on the page's low-level structure. This does not matter for Plain TEX or LATEX, where even most Lua-based packages don't depend on the node list structure; nevertheless, there are a few issues with ConTEXt.

However, on the Lua side, lua-widow-control modifies much of a page's internal structure. This should not affect any TEX code; however, it may surprise Lua code that modifies or depends on the page's low-level structure. This does not affect Plain TEX or LATEX where even most Lua-based packages don't depend on the node list structure. ConTEXt *does* depend on this internal node structure; however, I have carefully tested the package to ensure that this causes no issues.

Finally, keep in mind that adding lua-widow-control to a document will almost certainly change its page break locations.

Formats

Lua-widow-control runs on all known LuaTEX-based formats: Plain LuaTEX, LuaLATEX, ConTEXt MkIV, and OpTEX. Unless otherwise documented, all features should work equally well in all formats.

Lua-widow-control is also fully-compatible with the LuaMetaTEX-based formats: ConTEXt MkXL/LMTX, LuaMetaLATEX, and LuaMetaPlain. ConTEXt MkXL works equally well as ConTEXt MkIV and LuaLATEX; however, LuaMetaLATEX and

LuaMetaPlain support is still quite early. All features should work, although there are still a few minor bugs.

All told, lua-widow-control supports 7 different format/engine combinations.

Columns

Since TEX and the formats implement column breaking and page breaking through the same internal mechanisms, lua-widow-control removes widows and orphans between columns just as it does with widows and orphans between pages.

Lua-widow-control is known to work with the LATEX class option `twocolumn` and the two-column output routine from Chapter 23 of *The TEXBook*[4].

Performance

Lua-widow-control runs entirely in a single pass, without depending on any `.aux` files or the like. Thus, it shouldn't meaningfully increase compile times. Although lua-widow-control internally breaks each paragraph twice, modern computers break paragraphs near-instantaneously, so you are not likely to notice any slowdown.

ε-TEX penalties

Knuth's original TEX has three basic line penalties: `\interlinepenalty`, which is inserted between all lines; `\clubpenalty`, which is inserted after the first line; and `\widowpenalty`, which is inserted before the last line. The ε-TEX extensions generalize these commands with a syntax similar to `\parshape`: with `\widowpenalties` you can set the penalty between the last, second last, and *n*th last lines of a paragraph; `\interlinepenalties` and `\clubpenalties` behave similarly.

Lua-widow-control makes no explicit attempts to support these new `-penalties` commands. Specifically, if you give a line a penalty that matches either `\widowpenalty` or `\clubpenalty`, lua-widow-control will treat the lines exactly as it would a widow or orphan. So while these commands won't break lua-widow-control, they are likely to lead to some unexpected behaviour.

Grids

Lua-widow-control is fully compatible with the grid snapping features of ConTEXt ConTEXt MkIV and ConTEXt MkXL.

Footnotes

If there are footnotes (or any other type of inline `\insert`) present in the moved line, lua-widow-control will move both the "footnote mark" and the "footnote text" such that both are on the same page. However, this may lead to an odd blank space at the bottom of the page since lua-widow-control needs to move both the line and its footnotes. Footnotes cause the same page-breaking issues in unmodified Plain TEX and LATEX, so this is mostly unavoidable.

STABILITY

The documented interfaces of lua-widow-control can be considered stable: I'm not planning on removing or modifying any existing options or commands in any way that would break documents.

However, lua-widow-control's page breaking *is* subject to change. I will attempt to keep page breaks the same whenever reasonable; however, I will *rarely* make modifications to the algorithm when I can improve the output quality. Any such changes will be clearly noted in the release notes.

SHORT LAST LINES

When lengthening a paragraph with `\looseness`, it is common advice to insert ties (~) between the last few words of the paragraph to avoid overly-short last lines[4]. Lua-widow-control does this automatically, but instead of using ties or `\hbox`es, it uses the `\parfillskip` parameter. When lengthening a paragraph (and only when lengthening a paragraph—remember, lua-widow-control doesn't interfere with TEX's output unless it detects a widow or orphan), lua-widow-control sets `\parfillskip` to `0.75\hsize plus 0.05\hsize minus 0.75\hsize`. This normally makes the last line of a paragraph be at least 20% of the overall paragraph's width, thus preventing ultra-short lines.

KNOWN ISSUES

- When a three-line paragraph is at the end of a page forming a widow, lua-widow-control will remove the widow; however, it will leave an orphan. This issue is inherent to any process that removes widows through paragraph expansion and is thus unavoidable. Orphans are considered to be better than widows[5], so this is still an improvement.
- Lua-widow-control only attempts to expand paragraphs; it never attempts to shrink them. See the *TUGboat* article`<article>` §15.3 for further discussion. **(Issue #33)**
- Lua-widow-control can only expand paragraphs that fit completely on a page. This is unavoidable due to the one-page-at-a-time model: you can't modify the bottom half of a paragraph since its top half has already shipped out, and you can't expand the top half of a paragraph since that can't remove orphans. This

only causes issues if your document has paragraphs so long that a page only has two half-paragraphs and zero whole paragraphs.

- Sometimes a widow or orphan cannot be eliminated because no paragraph has enough stretch. Sometimes this can be remediated by increasing lua-widow-control's `\emergencystretch`; however, some pages just don't have any suitable paragraph.

  Long paragraphs with short words tend to be stretchier than short paragraphs with long words since these long paragraphs have more interword glue. Narrow columns also stretch more easily than wide columns since you need to expand a paragraph by less to make a new line.

- Lua-widow-control only attempts to expand paragraphs on a page with a widow or orphan. A global system like in *A general framework for globally optimized pagination*[6] would solve this; however, this is both NP-complete[7] and impossible to solve in a single pass. Very rarely would such a system remove widows or orphans that lua-widow-control cannot.

CONTRIBUTIONS

If you have any issues with lua-widow-control, please create an issue at the **project's GitHub page**. Or, if you think that you can solve any of the "**Known Issues**" or add any new features, **submit a PR**. Thanks!

CHANGELOG

All notable changes to lua-widow-control will be listed here, in reverse chronological order. **Changes listed in bold** are important changes: they either remove options or commands, or may change the location of page breaks.

v3.0.0 (2022-11-22)

- Add the new *TUGboat* and *Zpravodaj* articles.
- Add and document the public Lua interfaces.
- Change `\parfillskip` settings for lengthened paragraphs to more strongly prevent short last lines. **May affect page breaks.**
- Add the ability to configure the horizontal offset for the paragraph costs printed in draft mode.
- Add support for **LuaMetaLaTeX and LuaMetaPlain**. All features should work identically to the LuaTeX-based version, although there are a few minor bugs. (#40)
- Fully support inserts/footnotes in LuaMetaTeX (#38).
- Add support for presets in ConTeXt.
- Add support for node colouring in ConTeXt and OpTeX (#39).

v2.2.2 (2022-08-23)

- Add preliminary support for inserts/footnotes in LuaMetaTeX (#38).
- Use the built-in LaTeX key–value interface where available.

  This means that lua-widow-control now also reads the global class options.

- Add support for split footnotes (#37).

v2.2.1 (2022-07-28)

- Fix crashes with recent LuaMetaTeX (ConTeXt MkXL). See also **this thread**.
- No longer show "left parfill skip" warnings with ConTeXt LMTX/MkXL (#7).

v2.2.0 (2022-06-17)

- Fix paragraphs not being properly saved for potential expansion. **May affect page breaks.**
- Add a new `draft` option (**#36**).
- Fix a node memory leak (**#29**). You should now be able to use lua-widow-control on documents with > 10 000 pages.
- Use `\lua_load_module:n` when available.
- Add additional metadata to the documentation.

v2.1.2 (2022-05-27)

- Fully-support footnotes/inserts: lua-widow-control now moves the "footnote text" with the "footnote mark" when it moves a line to the next page.
- No longer attempt to expand paragraphs in `\vboxes`
- Minor documentation updates

v2.1.1 (2022-05-20)

- Prevent spurious `under/overfull \vbox` warnings when widows/orphans are removed
- Add TUGboat article to the distributed documentation
- Rewrite many portions of the manual
- Add support for `luahbtex` and `mmoptex` (**#35 @vlasakm**)
- Fix the (undocumented) `microtype` LaTeX option

v2.1.0 (2022-05-14)

- Fully support grid snapping in ConTeXt
- New warnings when a new widow/orphan is inadvertently created
- Significant internal rewrites
- Add Plain and OpTeX interfaces to `\nobreak` behaviour and debug mode

v2.0.6 (2022-04-23)

- Emergency fix for renamed LMTX engine Lua functions
- Internal LaTeX refactoring

v2.0.5 (2022-04-13)

- Support nested `\lwcdisablecmd` macros
- Fix `\lwcdisablecmd` in Plain TeX
- Support command patching in OpTeX
- Patch memoir to prevent spurious asterisks at broken two-line paragraphs (#32)

v2.0.4 (2022-04-07)

- Don't expand paragraphs typeset during output routines (#31)

v2.0.3 (2022-03-28)

- Automatically patch section commands provided by memoir, KOMA-Script, and titlesec.

v2.0.2 (2022-03-20)

Final release present in TeX Live 2021

- Add `balanced` mode preset.

v2.0.1 (2022-03-18)

- Documentation updates (#25)
- Bug fixes (#28)

v2.0.0 (2022-03-07)

- **Page breaks may be slightly different**
- **Removed `\lwcemergencystretch` and `\lwcdisablecmd` in LaTeX. Please use the new key–value interface**
- Use expl3 for the LaTeX files (#20)
- Use a key–value interface for configuration with LaTeX (#11)
- Silence some extraneous `luatexbase` info messages
- Add a "debug mode" to print extra information (#12)
- Fix error message line wrapping
- Don't reset `\interlinepenalty` and `\brokenpenalty`
- Set and analyze `\displaywidowpenalty`
- Keep section headings with moved orphans (#17)
- Add the ability to configure the maximum paragraph cost (#22)

- Add a "strict" mode
- Use an improved cost function to select the best paragraph to lengthen (#23)
- Dozens of bug fixes
- Miscellaneous documentation updates

v1.1.6 (2022-02-22)

- Add support for the OpTeX format/macro package.
- Add support for the LuaTeX/MKIV version of ConTeXt.
- Ensure compatibility with the new `linebreaker` package.
- Fix a small bug with `\lwcdisablecmd`.
- Test the `\outputpenalty` for the specific values that indicate a widow or orphan.

v1.1.5 (2022-02-15)

- Improve the appearance of the demo table in the documentation (#4)
- Improve compatibility with microtype
- Block loading the package without LuaTeX
- Improve logging
- Bug fix to prevent crashing

v1.1.4 (2022-02-04)

- Enable protrusion/expansion in the demo table in the documentation (#3)
- Fix `\prevdepth` bug

v1.1.3 (2022-01-30)

- Fix bug when used with the LaTeX `calc` package. (#2)

v1.1.2 (2021-12-14)

- Fix crash under ConTeXt LMTX

v1.1.1 (2021-11-26)

- Minor documentation updates

v1.1.0 (2021-11-08)

- Extensive documentation updates
- Clarify that lua-widow-control *does* in fact support columns

- Add `\lwcdisablecmd` macro to disable lua-widow-control for certain commands
- Automatically disable lua-widow-control inside section headings (uses `\lwcdisablecmd`)
- Add automated tests to prevent regressions
- Fix a rare issue that would cause indefinite hangs

v1.0.0 (2021-10-09)

Initial release

IMPLEMENTATION

From here and until the end of this manual is the raw source code of lua-widow-control. This is primarily of interest to developers; most users need not read further.

This code vaguely resembles the typical LaTeX literate programming style, although I use extensive inline comments instead of arcane docstrip macros. Hopefully this is useful as a reference for advanced lua-widow-control users as well as anyone doing extensive node manipulation in LuaTeX.

If want to offer any improvements to the code below, please open an issue or a PR on **GitHub**.

--- Silence the luatexbase "Enabling/Removing <callback>" info messages
---
--- Every time that a paragraph is typeset, \lwc/ hooks in
--- and typesets the paragraph 1 line longer. Some of these longer paragraphs
--- will have pretty bad badness values, so TeX will issue an over/underfull
--- hbox warning. To block these warnings, we hook into the `hpack_quality`
--- callback and disable it so that no warning is generated.
---
--- However, each time that we enable/disable the null `hpack_quality` callback,
--- luatexbase puts an info message in the log. This completely fills the log file
--- with useless error messages, so we disable it here.
---
--- This uses the Lua `debug` library to internally modify the log upvalue in the
--- `add_to_callback` function. This is almost certainly a terrible idea, but I
--- don't know of a better way to do it.

\starttext
    \Lwc/ can remove most widows and orphans from a document, \emph{without} stretching
      any glue or shortening any pages.

    It does so by automatically lengthening a paragraph on a page where a widow or
      orphan would otherwise occur. While \TeX{} breaks paragraphs into their natural
      length, \lwc/ is breaking the paragraph 1~line longer than its natural length.
      \TeX{}'s paragraph is output to the page, but \lwc/'s paragraph is just stored
      for later. When a widow or orphan occurs, \lwc/ can take over. It selects the
      previously-saved paragraph with the least badness; then, it replaces \TeX{}'s
      paragraph with its saved paragraph. This increases the text block height of the
      page by 1~line.
```

```
    Now, the last line of the current page can be pushed to the top of the next page.
      This removes the widow or the orphan without creating any additional work.
\stoptext
```
